Report Reference Number	EFDCAQAP2023
Date	TBA

Executive Summary

This draft Air Quality Action Plan (AQAP) has been produced as part of our statutory duties required by the Local Air Quality Management framework. It outlines the action we will take to improve air quality in Epping Forest District Council between 2023 to 2028.

This action plan replaces the previous action plan which ran from 2012 to 2014.

Projects delivered since the last action plan include:

- Optimising traffic flow through the Bell Common junction by adjusting the traffic signal timings
- Reduction of maximum speed through Epping Forest to 40 mph (to include the B1393 approaching the AQMA at Bell Common)
- Implementing anti idling legislation throughout the district
- Promoting clean air days
- Increasing monitoring throughout the District
- Introducing demand responsive transport

Air pollution is associated with a number of adverse health impacts. It is recognised as a contributing factor in the onset of heart disease and cancer. Additionally, air pollution particularly affects the most vulnerable in society: children and older people, and those with heart and lung conditions. There is also often a strong correlation with equalities issues, because areas with poor air quality are also often the less affluent areas^{1,2}.

The annual health cost to society of the impacts of particulate matter alone in the UK is estimated to be around £16 billion³. Epping Forest District Council is committed to

¹ Environmental equity, air quality, socioeconomic status and respiratory health, 2010

² Air quality and social deprivation in the UK: an environmental inequalities analysis, 2006

³ Defra. Abatement cost guidance for valuing changes in air quality, May 2013

reducing the exposure of people in the District to poor air quality in order to improve health.

We have developed actions that can be considered under 6 broad topics:

- Alternatives to private vehicle use/ promoting low/zero emission transport
- Environmental Permitting and other regulatory measures
- Freight and Delivery Management
- Policy Guidance and Development Management
- Promoting Low Emission Plant
- Public health, awareness raising and monitoring

In this AQAP we outline how we plan to address air quality issues within our control. However, we recognise that there are a large number of air quality policy areas that are outside of our influence (such as vehicle emissions standards agreed in Europe), but for which we may have useful evidence, and so we will continue to work with regional and central government on policies and issues beyond the Council's direct influence.

Responsibilities and Commitment

This AQAP was prepared by the Environmental Health team of Epping Forest District Council with the support and agreement of the following internal and external departments:

- Planning Team, Epping Forest District Council (EFDC)
- Licensing, EFDC
- Procurement, EFDC Building Regulations, EFDC
- Public Health, Community, Culture & Wellbeing, EFDC
- Sustainable Travel Team, EFDC
- Communications Team, EFDC
- Environmental Health, EFDC
- Highways Department, Essex County Council (ECC)
- Public Health, (Wellbeing, Public Health and Communities) ECC
- Sustainable Transport Team, ECC
- Trading Standards, ECC
- Qualis Group

This AQAP will be subject to an annual review. Progress each year will be reported in the Annual Status Reports (ASRs) produced by Epping Forest District Council, as part of our statutory Local Air Quality Management duties.

If you have any comments on this AQAP please send them to Environmental Health at:

Introduction

This report outlines the actions that Epping Forest District Council will deliver between 2023 to 2028 in order to reduce concentrations of air pollutants and exposure to air pollution; thereby positively impacting on the health and quality of life of residents and visitors to the District.

It has been developed in recognition of the legal requirement on the local authority to work towards Air Quality Strategy (AQS) objectives under Part IV of the Environment Act 1995 and relevant regulations made under that part and to meet the requirements of the Local Air Quality Management (LAQM) statutory process.

This Plan will be reviewed every five years at the latest and progress on measures set out within this Plan will be reported on annually within Epping Forest District Council's air quality Annual Status Report (ASR).

Summary of Current Air Quality in Epping Forest District Council

Air quality in the District is generally good with only small pockets of elevated concentrations of pollution related to vehicle emissions, which are limited to congested high street areas and busy junctions. The Council continues to monitor air quality across the District, using nitrogen dioxide as the key indicator.

Our monitoring shows that nitrogen dioxide concentrations across the District has for most of the monitoring locations in the District improved slightly. A significant improvement was experienced in 2020, however, it is most likely that this improvement is due to the national lockdown initiated by government in response to the COVID-19 pandemic, as these trends have been seen nationally.

The Council retains one small Air Quality Management Area (AQMA) near the B1393 / Theydon Road junction at Epping, Bell Common. The concentration of nitrogen dioxide measured during 2020 was $32.5\mu\text{g}/\text{m}^3$, significantly below both the $60\mu\text{g}/\text{m}^3$ concentration which is used to indicate that the hourly objective is likely to be exceeded, and the $40\mu\text{g}/\text{m}^3$ annual mean objective. In normal circumstances this would indicate that Council should consider the revocation of this management area, however as traffic volumes have returned to normal, it is not appropriate to consider such an action at present.

In January 2020 four additional nitrogen dioxide diffusion tube monitoring locations were set up. Two of these were close to residential receptors in the vicinity of Rectory Lane Loughton which experiences high volumes of traffic, and the other two were close to Nazeing crossroads, where queuing traffic is commonplace. As monitoring for these locations commenced during the pandemic, it is too early to make any conclusions with regards to pollution concentrations for these locations, however, monitoring has suggested that NO_2 concentrations at these locations are below the annual objective.

Further details with regards to our AQMA and pollution monitoring can be found on our Annual Status Reports found in <https://essexair.org.uk/>

Epping Forest District Council's Air Quality Priorities

The main pollution sources in our District continue to be vehicle emissions and emissions from buildings both domestic and commercial. Whilst the majority of the District experiences good air quality and complies with the current air quality standards set by the government, it's important to acknowledge that there is no safe exposure limit for certain pollutants like fine particulates.

The World Health Organization (WHO) has recently updated its guideline values which are lower than the air quality standards set out by our Government. We therefore aim to continue to improve air quality in our District and set an ambitious goal to work towards the WHO values.

To help us do this, we have set out priority measures within this AQAP that include:

1. Alternatives to private vehicle use/ promoting low/zero emission transport
2. Environmental Permitting and other regulatory measures
3. Freight and Delivery Management
4. Policy Guidance and Development Management
5. Promoting Low Emission Plant
6. Public health, awareness raising and monitoring

These are supported by the Council's Corporate Objectives:

- Reduce our carbon footprint across the District and within our council by working to reduce emissions, offsetting pollution by increasing tree planting including through new housing developments and community initiatives.
- Ensure all residents have the opportunity to lead healthy and fulfilling lives by delivering the objectives of the joint Health and Wellbeing Strategy and working with our colleagues in the NHS.

This draft Air Quality Action Plan (2023-2028) has been produced as part of our statutory duties under the Environment Act 1995, as required by the Local Air Quality Management (LAQM) framework.

1.1 Public Health Context

Air pollution is one of the largest environmental risk to public health in the UK. The annual mortality of human-made air pollution in the UK is roughly equivalent to between 28,000 and 36,000 deaths every year.⁴ It is estimated that between 2017 and 2025 the total cost to the NHS and social care system of air pollutants (fine particulate matter and nitrogen dioxide), for which there is more robust evidence for an association, will be £1.6 billion.⁵ Air pollution can cause and worsen health effects in all individuals, particularly society's most vulnerable populations. Long-term exposure to air pollution can cause chronic conditions such as cardiovascular and respiratory diseases as well as lung cancer, leading to reduced life expectancy. Short-term increases in levels of air pollution can also cause a range of health impacts, including effects on lung function, exacerbation of asthma, increases in respiratory and cardiovascular hospital admissions and mortality. Air pollution can affect anyone's health; nevertheless, some individuals can be more susceptible than others. These include children, the elderly, individuals with existing cardiovascular or respiratory diseases, pregnant women, communities in areas of higher pollution, such as close to busy roads and low-income communities.⁶

The Public Health Outcomes Framework (PHOF) examines indicators that help to understand trends in public health. It also enables local authorities to benchmark and compare their own outcomes with other local authorities. For example, one indicator looks at the health impacts of air pollution: the fraction (%) of mortality attributable to long-term exposure to PM_{2.5}. This is calculated using modelled PM_{2.5} levels. Based on the PHOF indicator as seen in table 3.1(a) below, Epping Forest District is above the England average of 5.1% under the old method for assessing this indicator at 5.9%. The District is also above the England average of 5.6% using the new method for assessing this indicator at 6.1%.

⁴ <https://www.gov.uk/government/publications/air-pollution-applying-all-our-health/air-pollution-applying-all-our-health>

⁵ <https://www.gov.uk/government/publications/air-pollution-applying-all-our-health/air-pollution-applying-all-our-health>

⁶ <https://www.gov.uk/government/publications/air-pollution-applying-all-our-health/air-pollution-applying-all-our-health>

Table 3.1(a): Fraction (%) of mortality attributable to long-term exposure to PM_{2.5} for Epping Forest using old and new method

Indicator	Period	Epping For			England				
		Recent Trend	Count	Value	Value	Worst/ Lowest	Range	Best/ Highest	
Fraction of mortality attributable to particulate air pollution									
Fraction of mortality attributable to particulate air pollution (old method)	2019	–	-	5.9%	5.1%	2.6%		7.0%	
Fraction of mortality attributable to particulate air pollution (new method)	2020	–	-	6.1%	5.6%	3.0%		7.8%	

Whilst the District is above the England average for mortality attributable to long-term exposure to PM_{2.5}, the percentage has reduced since 2018 as seen in table 3.1(b) below. This is in line with reductions seen nationally.

Table 3.1(b): Trend of fraction (%) of mortality attributable to long-term exposure to PM_{2.5} using the new method for Epping Forest in the past 3 years

Period	Epping Forest					East of England	England
	Count	Value	95% Lower CI	95% Upper CI			
2018	○	-	8.0%	-	-	7.6%	7.1%
2019	○	-	8.1%	-	-	7.6%	7.1%
2020	○	-	6.1%	-	-	5.8%	5.6%

Table 3.1(c) below, shows where Epping Forest District Council stands in comparison to neighbouring boroughs with regards to mortality attributable to long-term exposure to PM_{2.5} using the new method for neighbouring authorities. Whilst the District does not have the highest mortality attributable to long-term exposure to PM_{2.5} as compared to neighbouring authorities, it does still have a high value. Furthermore, as more research confirms the negative health impacts associated with exposure to particulates, the Council acknowledges that more needs to be done both on a local and national scale to reduce particulate exposure. Our actions in table 5.1 below demonstrate what the council is doing to reduce particulate emissions and exposure in our District.

Table 3.1(c): Trend of fraction (%) of mortality attributable to long-term exposure to PM_{2.5} using the new method for neighbouring authorities

Authority	2020 value (%) new method
Thurrock Council	6.5%
Basildon Borough Council	6.2%
Castle Point Borough Council	6.1%
Epping Forest District Council	6.1%
Southend-on-Sea City Council	6.1%
Brentwood Borough Council	6.0%
Chelmsford City Council	5.9%
Colchester City Council	5.9%
Harlow Council	5.9%
Rochford District Council	5.9%
Braintree District Council	5.7%
Maldon District Council	5.7%
Tendring District Council	5.6%
Uttlesford District Council	5.5%

1.2 Air Quality Focus Areas for PM_{2.5}

In addition to implementing actions to improve air quality within our AQMA, the Council has also created air quality focus areas (AQFA) for PM_{2.5} exposure. AQFA's have normally been locations that not only exceed the EU annual mean limit value for NO₂ but are also locations with high human exposure. We wanted to use a similar concept to create focus areas for PM_{2.5} as that is the pollutant used in the Public Health Indicator for assessing mortality attributable to long-term exposure.

Under the Strategic Health Asset Planning and Evaluation (SHAPE) platform, The UK Health Security Agency has developed a pilot indicator to represent population level vulnerability to air pollution at Lower-layer Super Output Areas level. This is a ranking of the level of vulnerability from low (1-2) to high (9-10) decile scores. This is based on the population characteristics (% of young people (<16 years) and older adults (65+ years)), Levels of Deprivation (Index of multiple deprivation score), location of vulnerable populations (any hospitals, schools, care homes and childcare facilities) and the concentration of air pollution (NO₂ and PM_{2.5}) modelled for 2018.

Based on SHAPE's air pollution vulnerability indicator for PM_{2.5}, we have chosen locations with the highest scores 9 and 10 as our AQFA's. These are represented in

figure 3.2 below with the darkest shades. As seen below, most of the areas with the highest pollution vulnerability scores are also the areas closest to main roads such as the M11, M25.

As this is a pilot indicator, we are conducting district wide air quality modelling which will help to confirm of the results from the SHAPE platform. The modelling will be completed by April 2023 and the pollution vulnerability map will be updated accordingly.

A full list of districts with a high pollution vulnerability score is provided in Appendix A.

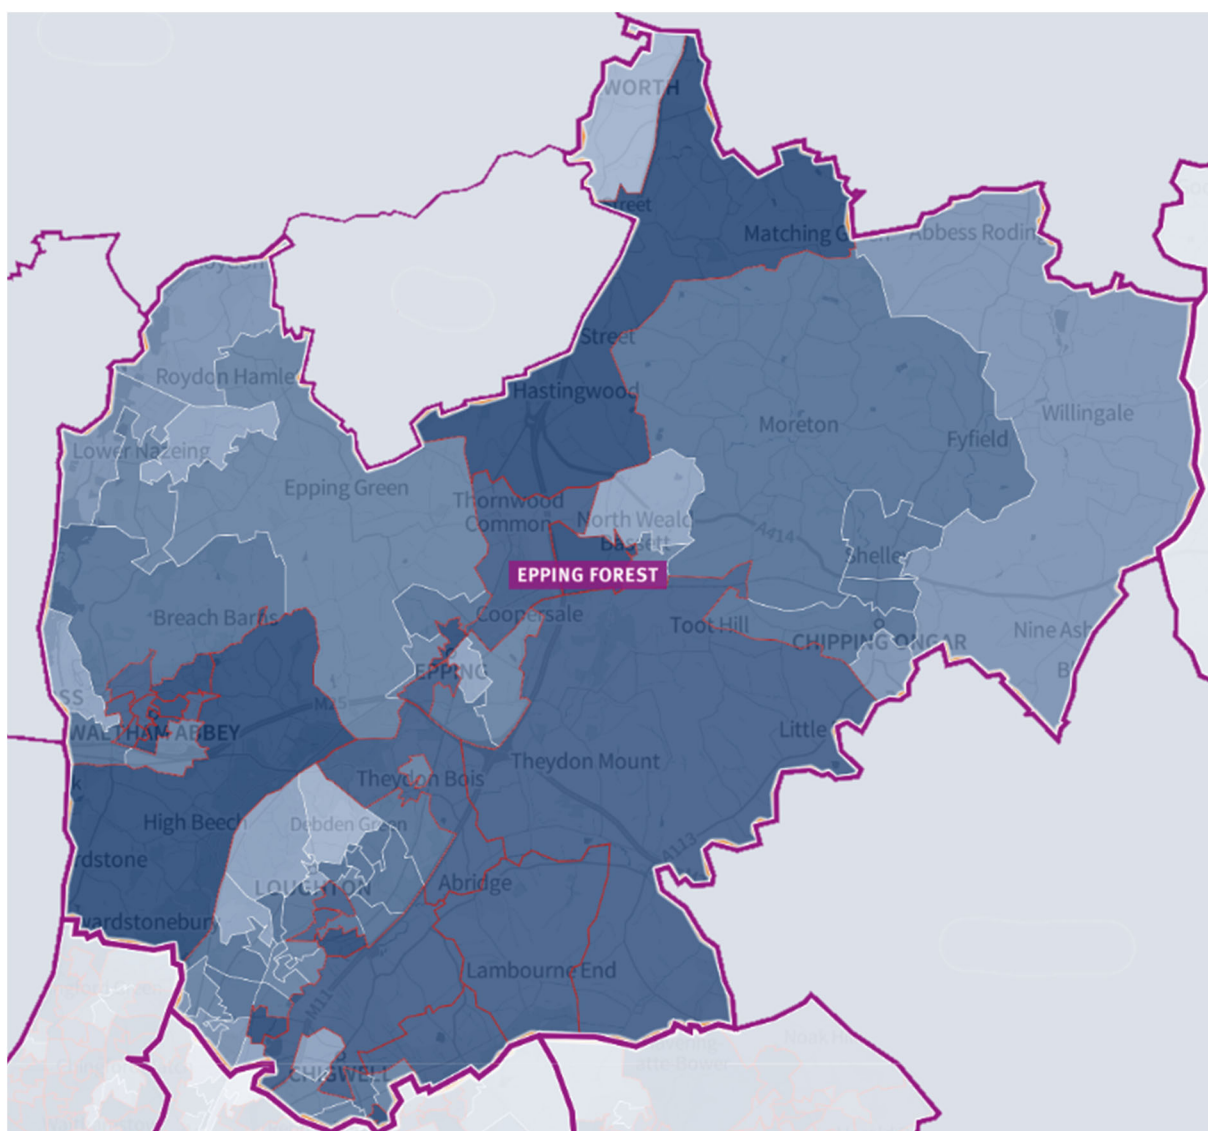

Figure 3.2: Air Pollution Vulnerability Indicator for PM_{2.5}

1.3 Planning and Policy Context

The planning regime continues to be a main tool for the Council with regards to improving air quality. Whilst our Local Plan has yet to be adopted and is currently being reviewed by the planning inspector, the Council has ensured that air quality both with regards to human health and the Epping Forest Special Area of Conservation (EFSAC) is considered material consideration within the planning regime. Most large applications require an air quality assessment (detailed or screening) to ensure that new developments are not contributing to poor air quality in the District as well as not introducing new receptors to areas of poor air quality. A Habitats Regulation Assessment (HRA) is also required to ensure developments do not negatively impact on the EFSAC.

Whilst a London policy, the Council is also looking at air quality neutral options to address both vehicle as well as building emissions from new developments. This will ensure that new developments do not negatively impact on local air quality or contribute to an increasing pollution baseline, also known as creeping pollution baseline. This not only benefits air quality in the District but also helps with regards to the Council's commitment to become carbon neutral by 2030.

The Council is also focussing on construction impacts and working to reduce emissions from site by working with developers to ensure robust measures are put in place via planning conditions to limit emissions from the demolition, earthworks, construction and track out phases of a development. Whilst we can currently address emissions from construction activities, we have no powers with regards to emissions from non road mobile machinery (NRMM) which can contribute a significant amount of emissions to local air quality. At the moment, we are encouraging developers to adopt measures within the London Plan that require a specific emission standards from NRMM's. At present, we do not have enforcement powers with regards to NRMM. Legislation from central government with respect to this matter would be greatly welcomed.

1.4 Source Apportionment

The AQAP measures presented in this report are intended to be targeted towards the main sources of emissions within the District; these are vehicle and building emissions.

In 2021 the Council commissioned Bureau Veritas to produce a detailed modelling and source apportionment assessment to support the update of this Air Quality Action Plan. The detailed modelling assessment focussed on the road network within and around the Epping Forest AQMA to establish concentrations and determine the sources that contribute to pollutant concentrations within the AQMA. It assessed NO₂, PM₁₀ and PM_{2.5} concentrations.

Amongst its conclusions, the assessment determined that:

- the main pollution source contributing to the AQMA came from vehicle emissions
- the background concentrations show that for NO_x, motorway emissions account for around half of background concentrations
- within the AQMA, congestion accounted for 81.9% of NO_x contributions from the road and that traffic smoothing measures would help to reduce this pollution contribution
- petrol cars were the most prevalent vehicles on the road within the AQMA, with 46.6% of all vehicles within the assessment being petrol cars
- the NO_x source apportionment exercise demonstrated that diesel cars and diesel light good vehicles (LGVs) were the primary contributors to local road NO_x concentrations within the AQMA
- PM₁₀ and PM_{2.5} concentrations within the AQMA are largely made up of residual background sources. For both pollutants, the greatest road contributor was identified as being Diesel Cars, followed by Petrol cars and Diesel LGVs
- the estimated year of compliance within the AQMA, should no additional measures be put in place, is 2024 and will be below 10% of the air quality objectives (AQO) by 2026.

Whilst the assessment concluded that the AQMA should comply with the AQO by 2024 without any measures, the Council will still be delivering air pollution reduction measures to ensure that our District not only complies with the air quality standards but also works towards the World Health Organization air quality guidelines and helps towards our Climate Change Action Plan as well as improving air quality around the Epping Forest Special Area of Conservation.

The full detailed modelling and source apportionment assessment can be found in Appendix B of this AQAP. Additionally, all our ASR's can be found on the Essex Air website: <https://essexair.org.uk>

1.5 Greater London Authority's proposed Ultra Low Emission Zone expansion

In the summer of 2022, the Greater London Authority (GLA) via Transport for London (TfL) consulted on the possibility of expanding the Ultra Low Emission Zone (ULEZ) to cover most of the Great London area. Whilst the consultation information was detailed, it failed to demonstrate that our AQMA would not be negatively impacted by the proposed expansion. Because of this, the 2024 estimated date of compliance of our AQMA may be delayed to a later date. Monitoring of our AQMA will continue until a time that we are certain that levels are below the limit values. Revocation of our AQMA will not occur until we have confirmed with Defra that it is the appropriate step to take. Our full response to the GLA's proposed ULEZ expansion is included in Appendix C.

Development and Implementation of Epping Forest District Council's AQAP

1.6 Consultation and Stakeholder Engagement

Once approved by Scrutiny, the draft AQAP will be circulated to neighbouring local authorities and statutory consultees for comment. We will also engage with the local community and businesses for additional feedback to be considered in the final AQAP document. Engagement will occur via email, social media and our website and will last for a minimum of four-weeks.

A summary of the responses to the consultation will be published in the final AQAP document.

1.7 Steering Group

In the production of this AQAP, the following stakeholders contributed to the creation of the measures within table 5.1.

Internal:

- Planning Team, Epping Forest District Council (EFDC)
- Licensing, EFDC
- Procurement, EFDC
- Public Health, Community, Culture & Wellbeing, EFDC
- Sustainable Travel Team, EFDC
- Communications Team, EFDC
- Environmental Health, EFDC

External:

- Highways Department, Essex County Council (ECC)
- Public Health, (Wellbeing, Public Health and Communities) ECC
- Sustainable Transport Team, ECC
- Trading Standards, ECC
- Qualis Group

AQAP Measures

Table 0.1 below shows Epping Forest District Council's AQAP measures. It contains:

- a list of the actions that form part of the plan
- the responsible individual and departments/organisations who will deliver this action
- estimated cost of implementing each action (overall cost and cost to the local authority)
- expected benefit in terms of pollutant emission and/or concentration reduction
- the timescale for implementation
- how progress will be monitored

NB: Please see future ASRs for regular annual updates on implementation of these measures

Table 0.1 – Air Quality Action Plan Measures

Measure No.	Measure	Timescale	Organisations Involved	Funding Source	Defra AQ Grant Funding	Cost Low - <£5K Medium - £5-20K High - £20K +	Expected Benefit	Key Performance Indicator	Comments / Potential Barriers / Progress

Executive Summary

Purpose of Assessment

Bureau Veritas has been commissioned by Epping Forest District Council (the Council) to complete a Detailed Modelling and Source Apportionment Assessment to support the update of their Air Quality Action Plan (AQAP). Currently there is one Air Quality Management Area (AQMA) within Epping Forest, declared in 2008 as a result of exceedances of the $40 \mu\text{g}/\text{m}^3$ annual mean and $200 \mu\text{g}/\text{m}^3$ 1-hour objectives for Nitrogen Dioxide (NO_2). This AQMA is located near the B1393/Theydon Road junction at Epping, Bell Common. The aim of this Detailed Modelling Assessment is to increase the Councils' understanding of pollutant concentrations within the Epping Forest District AQMA, in order to provide technical input into their forthcoming AQAP.

The Detailed Modelling Assessment focusses on the road network within and around the Epping Forest AQMA to establish concentrations and determine the sources that contribute to pollutant concentrations within the AQMA. The area was modelled using the advanced atmospheric dispersion model ADMS-Roads (Version 5.0.0.1) and latest emissions from the Emissions Factors Toolkit (Version 10.1), with annual mean NO_2 concentration outputs produced at two discrete receptor locations, and across a receptor grid.

Assessment Findings

The highest annual mean concentration of NO_2 was recorded at R1 with a concentration of $52.2 \mu\text{g}/\text{m}^3$. This is slightly higher than the adjacent recorded monitoring which recorded $48 \mu\text{g}/\text{m}^3$ as a result of a slightly lower modelling height and its position relative to the road but still demonstrated an exceedance of the air quality objective limit of $40 \mu\text{g}/\text{m}^3$.

The empirical relationship given in LAQM.TG(16)¹ states that exceedances of the 1-hour mean objective for NO_2 is only likely to occur where annual mean concentrations are $60 \mu\text{g}/\text{m}^3$ or above at a location of relevant exposure (Table 2-1). Given the NO_2 annual mean concentration recorded at all receptors is below $60 \mu\text{g}/\text{m}^3$, exceedances of the hourly NO_2 AQS objective are unlikely.

PM_{10} and $\text{PM}_{2.5}$ concentrations have also been predicted as part of the modelling assessment. No modelled receptors recorded concentrations in exceedance of either of the annual mean objectives for these pollutants. The highest modelled PM_{10} concentration was $20.6 \mu\text{g}/\text{m}^3$ at R1. The highest modelled $\text{PM}_{2.5}$ concentration was $12.9 \mu\text{g}/\text{m}^3$ at R1.

Estimated Year of Compliance

Using the recommended method in TG(16), the estimated year of compliance within the AQMA, should no additional measures be put in place, is 2024 and will be below 10% of the AQO by 2026. It should be noted that this estimate is based on assumptions that were correct prior to the COVID-19 pandemic which is likely to affect behaviour and vehicle fleet predictions, so this result should be treated with some caution.

Source Apportionment

To help inform the development of measures as part of a future AQAP, a source apportionment exercise was undertaken to provide an understanding of any potential similarities in vehicle emission contributors within the AQMA. The source apportionment exercise has considered concentrations of oxides of Nitrogen (NO_x) and Particulate Matter measuring 10 microns and below (PM_{10}) and 2.5 microns and below ($\text{PM}_{2.5}$).

Petrol Cars were the most prevalent vehicles on the road within the AQMA, 46.6% of all vehicles were petrol cars. The fleet makeup, as determined by the ANPR survey, also indicated that vehicles using High Road Epping were made up of older vehicles than the default fleet assumption within the EFT derived from the National Air Emissions Inventory (NAEI).

The background concentrations show that for NO_x, motorway emissions account for around half of background concentrations.

The NO_x source apportionment exercise demonstrates Diesel Cars and Diesel Light Good Vehicles (LGVs) being the primary contributors to local road NO_x concentrations within the AQMA. The split between overall car, LGV and Heavy Good Vehicles (HGV) emissions was roughly equal with each contributing around a third to total road NO_x.

An assessment of queueing traffic showed that, within the AQMA, congestion accounts for 81.9% of NO_x contributions from the road. This is to be expected as the receptors is located adjacent to traffic lights. Should any traffic smoothing measures such as replacing the lights with a roundabout be introduced, this is likely to reduce pollutant concentrations within the AQMA.

PM₁₀ and PM_{2.5} concentrations within the AQMA are largely made up of residual background sources. For both pollutants, the greatest road contributor was identified as being Diesel Cars, followed by Petrol cars and Diesel LGVs.

1 Introduction

Bureau Veritas has been commissioned by Epping Forest District Council (the Council) to complete a Source Apportionment Assessment to update their outdated Air Quality Action Plan (AQAP). Currently there is one Air Quality Management Area (AQMA) within Epping Forest, declared as a result of exceedances of the 40 µg/m³ annual mean and 200 µg/m³ 1-hour objectives for Nitrogen Dioxide (NO₂). This AQMA is located near the B1393/Theydon Road junction at Epping, Bell Common.

In order to provide technical input into an updated AQAP that will cover the area within the existing AQMA boundary, the air quality modelling has been completed using 2019 traffic data, 2019 monitoring data and the latest Local Air Quality Management (LAQM) tools. This report details the findings of this updated analysis, and provides recommendation on matters related to NO₂ exceedances, in order to inform the update of the AQAP.

1.1 Scope of Assessment

It is the general purpose and intent of this assessment to determine, with reasonable certainty, the magnitude and geographical extent of any exceedances of the AQS objectives for NO₂, enabling the Council to provide for a focused consideration on updating measures as part of the revision of the AQAP.

The following are the objectives of the assessment:

- To assess the air quality at selected locations (“receptors”) representative of worst-case exposure relative to the averaging period of focus (i.e. annual objective - façades of the existing residential units), based on modelling of emissions from road traffic on the local road network;
- To establish the spatial extent of any likely exceedances of the UK annual mean NO₂ AQS objective limit, and to identify the spatial extent of any areas within 10%;
- To establish the required reduction in emissions to comply with the UK AQS objectives; and
- To determine the relative contributions of various source types to the overall pollutant concentrations within the new AQMA, through source apportionment, in order to inform an updated AQAP.

The approach adopted in this assessment to assess the impact of road traffic emissions on air quality utilised the atmospheric dispersion model ADMS-Roads version 5.0.0.1, focusing on emissions of oxides of nitrogen (NO_x), which comprise of nitric oxide (NO) and nitrogen dioxide (NO₂). Particulate Matter (PM₁₀ and PM_{2.5}) emissions have also been considered for completeness.

In order to provide consistency with the Council’s own work on air quality, the guiding principles for air quality assessments, as set out in the latest guidance provided by Defra for air quality assessment (LAQM.TG(16))¹, have been used.

¹ LAQM Technical Guidance LAQM.TG(16) – April 2021. Published by Defra in partnership with the Scottish Government, Welsh Assembly Government and Department of the Environment Northern Ireland.

2 Air Quality – Legislative Context

2.1 Air Quality Strategy

The importance of existing and future pollutant concentrations can be assessed in relation to the national air quality standards and objectives established by Government. The Air Quality Strategy² (AQS) provides the over-arching strategic framework for air quality management in the UK and contains national air quality standards and objectives established by the UK Government and Devolved Administrations to protect human health. The air quality objectives incorporated in the AQS and the UK Legislation are derived from Limit Values prescribed in the EU Directives transposed into national legislation by Member States.

The CAFE (Clean Air for Europe) programme was initiated in the late 1990s to draw together previous directives into a single EU Directive on air quality. The CAFE Directive³ has been adopted and replaces all previous air quality Directives, except the 4th Daughter Directive⁴. The Directive introduces new obligatory standards for PM_{2.5} for Government but places no statutory duty on local government to work towards achievement of these standards.

The Air Quality Standards (England) Regulations⁵ 2010 came into force on 11 June 2010 in order to align and bring together in one statutory instrument the Government's obligations to fulfil the requirements of the new CAFE Directive.

The objectives for ten pollutants – benzene (C₆H₆), 1,3-butadiene (C₄H₆), carbon monoxide (CO), lead (Pb), nitrogen dioxide (NO₂), sulphur dioxide (SO₂), particulate matter (PM₁₀ and PM_{2.5}), ozone (O₃) and Polycyclic Aromatic Hydrocarbons (PAHs), have been prescribed within the AQS².

The AQS objectives apply at locations outside buildings or other natural or man-made structures above or below ground, where members of the public are regularly present and might reasonably be expected to be exposed to pollutant concentrations over the relevant averaging period. Typically, these include residential properties and schools/care homes for long-term (i.e. annual mean) pollutant objectives and high streets for short-term (i.e. 1-hour) pollutant objectives. Table 2-1 taken from LAQM TG(16)¹ provides an indication of those locations that may or may not be relevant for each averaging period.

This assessment focuses on NO₂ due to the significance this pollutant holds within the Council's administrative area - evidenced by the declared AQMA. Moreover, as a result of traffic pollution the UK has failed to meet the EU Limit Values for this pollutant by the 2010 target date. As a result, the Government has had to submit time extension applications for compliance with the EU Limit Values, which has since passed and its continued failure to achieve these limits is currently giving rise to infraction procedures being implemented. The UK is not alone as the challenge of NO₂ compliance at EU level includes many other Member States.

In July 2017, the Government published its plan for tackling roadside NO₂ concentrations⁶, to achieve compliance with EU Limit Values. This sets out Government policies for bringing NO₂ concentrations within statutory limits in the shortest time period possible. Furthermore, the Clean Air Strategy was published in 2019, which outlines how the UK will meet international commitments relating to arsenic, cadmium, mercury, nickel and polycyclic hydrocarbons in ambient air.

³ Directive 2008/50/EC of the European Parliament and of the Council of 21 May 2008 on ambient air quality and cleaner air for Europe.

⁴ Directive 2004/107/EC of the European Parliament and of the Council of 15 December 2004

⁵ The Air Quality Standards Regulations (England) 2010, Statutory Instrument No 1001, The Stationary Office Limited.

⁶ Defra, DfT (2017), UK plan for tackling roadside nitrogen dioxide concentrations

to significantly reduce emissions of five damaging air pollutants by 2020 and 2030 under the adopted revised National Emissions Ceiling Directive (NECD).

The AQS objectives for these pollutants are presented in [Table 2-2](#).

Table 2-1 – Examples of where the Air Quality Objectives should apply

Averaging Period	Objectives should apply at:	Objectives should generally not apply at:
Annual mean	All locations where members of the public might be regularly exposed. Building facades of residential properties, schools, hospitals, care homes etc.	Building facades of offices or other places of work where members of the public do not have regular access. Hotels, unless people live there as their permanent residence. Gardens of residential properties. Kerbside sites (as opposed to locations at the building façade), or any other location where public exposure is expected to be short term
24-hour mean and 8-hour mean	All locations where the annual mean objectives would apply, together with hotels. Gardens or residential properties ¹ .	Kerbside sites (as opposed to locations at the building façade), or any other location where public exposure is expected to be short term.
1-hour mean	All locations where the annual mean and 24 and 8-hour mean objectives would apply. Kerbside sites (e.g. pavements of busy shopping streets). Those parts of car parks, bus stations and railway stations etc. which are not fully enclosed, where the public might reasonably be expected to spend one hour or more. Any outdoor locations at which the public may be expected to spend one hour or longer.	Kerbside sites where the public would not be expected to have regular access.
15-minute mean	All locations where members of the public might reasonably be expected to spend a period of 15 minutes or longer.	

Note ¹ For gardens and playgrounds, such locations should represent parts of the garden where relevant public exposure is likely, for example where there is seating or play areas. It is unlikely that relevant public exposure would occur at the extremities of the garden boundary, or in front gardens, although local judgement should always be applied.

Table 2-2 – Relevant AQS Objectives for the Assessed Pollutants in England

Pollutant	AQS Objective	Concentration Measured as:	Date for Achievement
Nitrogen dioxide (NO ₂)	200 µg/m ³ not to be exceeded more than 18 times per year	1-hour mean	31 st December 2005
	40 µg/m ³	Annual mean	31 st December 2005
Particles (PM ₁₀)	50 µg/m ³ not to be exceeded more than 35 times a year	24-hour mean	31 st December 2004
	40 µg/m ³	Annual Mean	31 st December 2004
Particles (PM _{2.5})	25 µg/m ³	Annual Mean	2020

2.2 Local Air Quality Management (LAQM)

Part IV of the Environment Act 1995⁷ places a statutory duty on local authorities to periodically review and assess air quality within their area, and determine whether they are likely to meet the AQS objectives set down by Government for a number of pollutants – a process known as Local Air Quality Management (LAQM). The AQS objectives that apply to LAQM are defined for seven pollutants: benzene, 1,3-butadiene, CO, Pb, NO₂, SO₂ and Particulate Matter.

Local Authorities were formerly required to report on all of these pollutants, but following an update to the regime in 2016, the core of LAQM reporting is now focussed around the objectives of three pollutants: NO₂, PM₁₀ and SO₂. Where the results of the Review and Assessment process highlight that problems in the attainment of the health-based objectives pertaining to the above pollutants will arise, the authority is required to declare an AQMA – a geographic area defined by high concentrations of pollution and exceedances of health-based standards.

The areas in which the AQS objectives apply are defined in the AQS as locations outside (i.e. at the façade) of buildings or other natural or man-made structures above or below ground where members of the public are regularly present and might reasonably be expected to be exposed to pollutant concentrations over the relevant averaging period of the AQS objective.

Following any given declaration, the Local Authority is subsequently required to develop an Air Quality Action Plan (AQAP), which will contain measures to address the identified air quality issue and bring the location into compliance with the relevant objective as soon as possible.

One of the objectives of the LAQM regime is for local authorities to enhance integration of air quality into the planning process. Current LAQM Policy Guidance⁸ recognises land-use planning as having a significant role in term of reducing population exposure to elevated pollutant concentrations. Generally, the decisions made on land-use allocation can play a major role in improving the health of the population, particularly at sensitive locations – such as schools, hospitals and dense residential areas.

3 Review and Assessment of Air Quality Undertaken by the Council

3.1 Local Air Quality Management

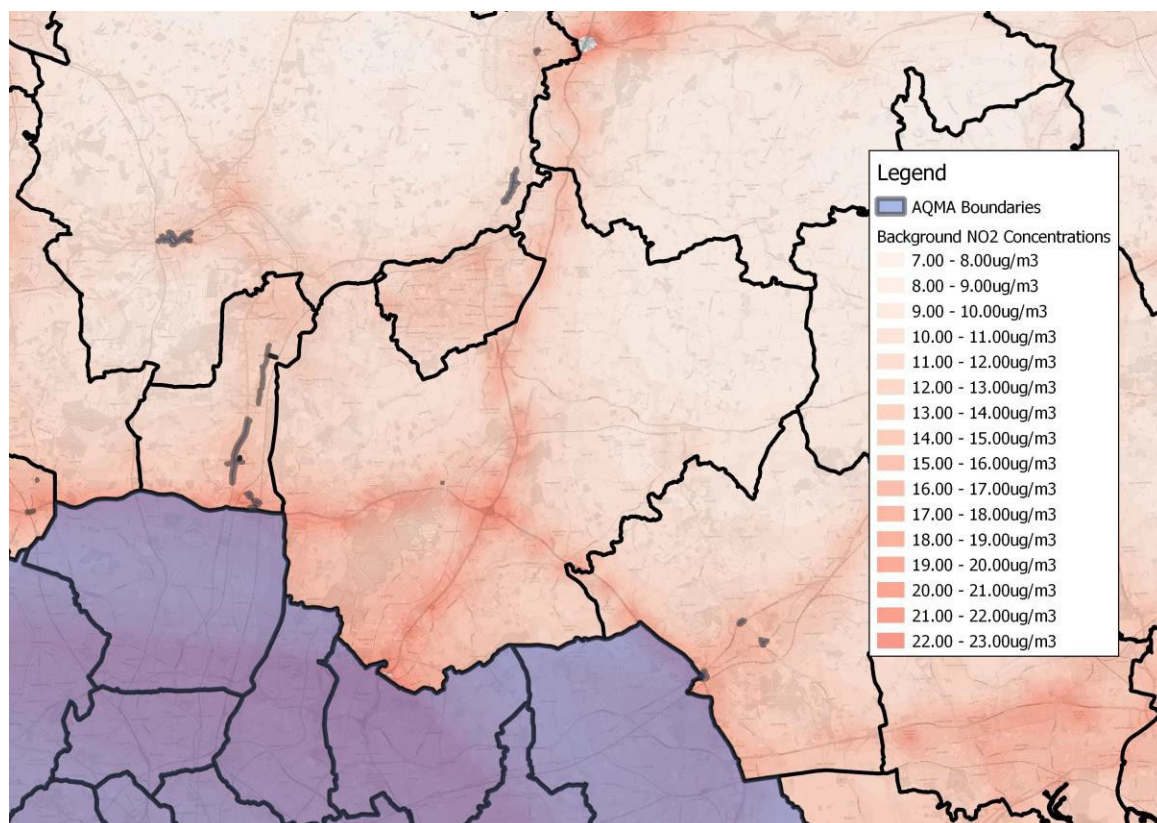

The Council currently has one AQMA (AQMA Epping Forest District Council No.2 2012), declared in 2008 for the exceedance of the NO₂ annual mean UK AQS objective of 40 µg/m³ and 1-hour mean objective. The AQMA, as shown in Figure 3-2, is located near the B1393/Theydon Road junction at Epping, Bell Common.

The most recent AQAP for this AQMA was published in 2012. Monitoring within the borough has shown that concentrations of NO₂ are generally declining. In the most recently available Annual Status Report (ASR), the only monitored exceedance of the NO₂ annual mean AQS objective was within the existing AQMA.

Every local authority that has an active AQMA, is required under Part IV of the Environment Act 1995 and Part III of the Environment (NI) Order 2002 to provide an AQAP as a means to address the areas of poor air quality that have been identified within the AQMA. Nonetheless, the specifications for this tender only detail the requirement for source apportionment study to be undertaken. As a result, the proposal herein has focussed on the proposed scope for a source apportionment study.

From an initial review of background annual mean NO₂ concentrations as shown in Figure 3-1, the M25 and M11 corridors are key contributors to pollutant concentrations within the district as pictured below, the darker red highlighting the higher concentrations.

Figure 3-1 – Background NO₂ Concentrations in EFDC

3.2 Review of Air Quality Monitoring

3.2.1 Local Air Quality Monitoring

During 2019, the latest available year of baseline monitoring, the Council's non-automatic monitoring programme consisted of recording NO₂ concentrations using a network of passive diffusion tubes at 42 sites across Epping Forest District. No automatic (continuous) monitoring took place within the District during 2019.

Between 2015 and 2020 there have been exceedances of the annual mean AQS objective at Sites; 1, 3 and 11 as set out in the latest ASR available for EFDC⁹. During 2019, there was only one recorded exceedance of the annual mean AQS objective for NO₂ at Site 3: Bell Vue which monitored 48 µg/m³.

The details of the diffusion tube monitoring within Epping for 2019 used for the purpose of the modelling assessment are shown in Table 3-1, and monitored concentrations for 2015-2019 are presented in Table 3-2.

Table 3-1 – Epping Forest District Council LAQM Diffusion Tube Monitoring

Site ID	Site Location	Site Type	In AQMA	OS Grid Ref X	OS Grid Ref Y	Monitoring Height (m)
3	Epping: Bell Vue	Roadside	Y	544928	201281	2
33	Epping: Copped Hall, Bell Common	Roadside	N	544709	201139	2

Table 3-2 – Relevant Epping Forest District Council LAQM Diffusion Tube Monitoring

Site ID	Valid Data Capture for 2019 (%)	Annual Mean NO ₂ Concentration (µg/m ³)				
		2015	2016	2017	2018	2019
1	100.0	39	48	45	39	39
11	100.0	45	42	39	39	34
3	100.0	63	64	64	55	48
33	75.0	-	-	-	-	31

Notes
All values reported are bias adjusted as required and represent the monitoring location (i.e. absence of distance correction calculations)

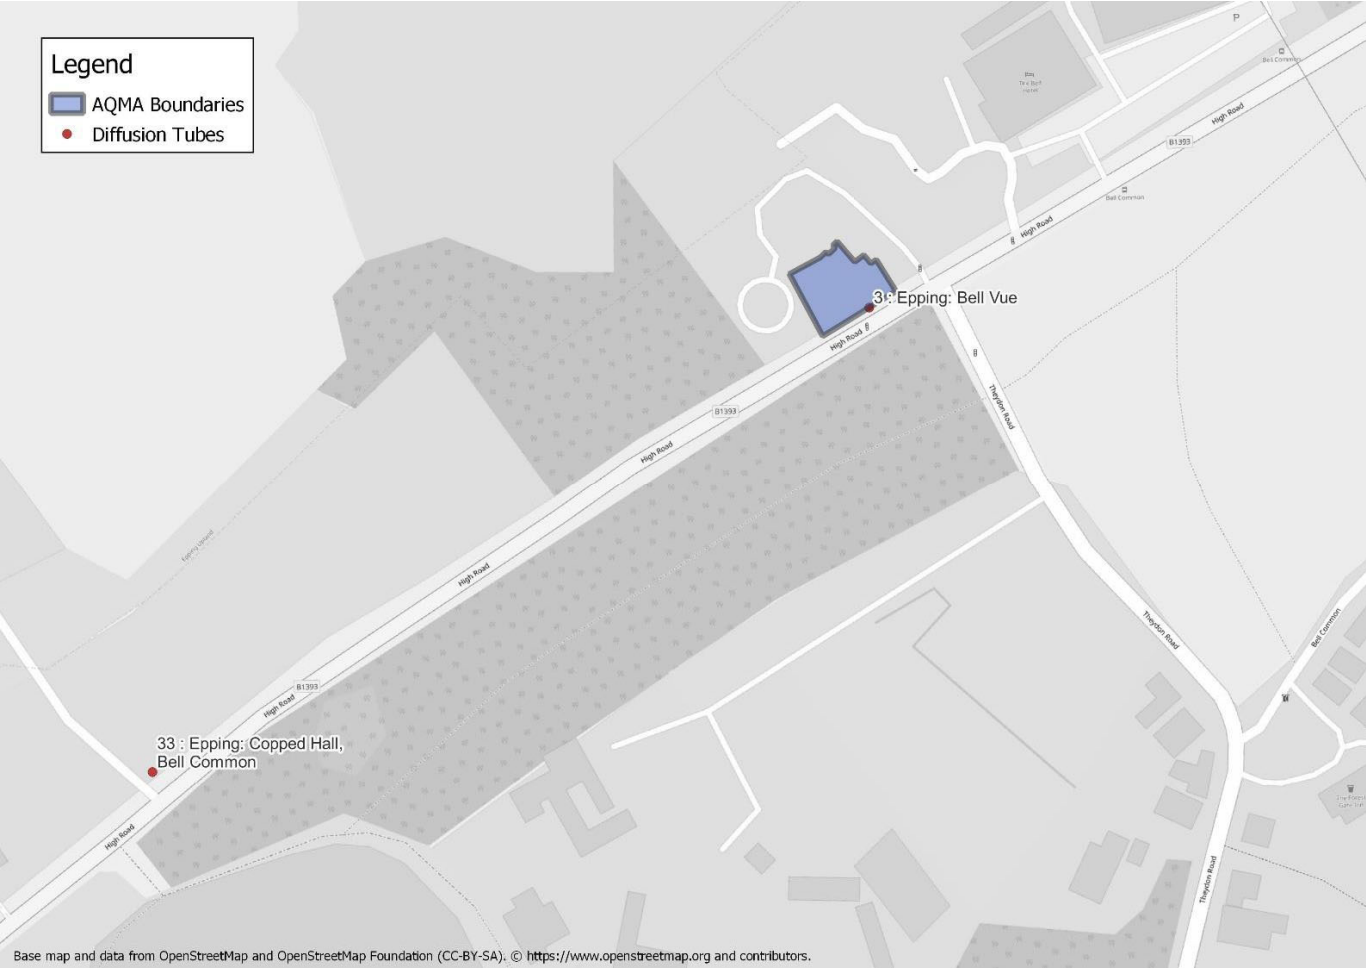

The only monitored exceedance of the annual average NO₂ limit was at location 3 which has recorded an exceedance every year since 2015. Monitoring at site 33 commenced in 2019 so there are no historical data available for this site.

The empirical relationship given in LAQM.TG(16)¹ states that exceedances of the 1-hour mean objective for NO₂ is only likely to occur where annual mean concentrations are 60 µg/m³ or above at a location of relevant exposure (Table 2-1). This indicates that an exceedance of the 1-hour mean objective is unlikely to have occurred at these sites past 2017 at location 3.

Epping Forest District Council AQMA boundary and the relevant 2019 council-operated monitoring locations are presented in [Figure 3-2](#).

3.3 Defra Background Concentration Estimates

Defra maintains a nationwide model of existing and future background air pollutant concentrations at a 1 km x 1 km grid square resolution. This data includes annual average concentration for NO_x, NO₂, PM₁₀ and PM_{2.5}, using a base year of 2018 (the year in which comparisons between modelled and monitoring are made)¹⁰. The model used to determine the background pollutant levels is semi-empirical in nature: it uses the National Atmospheric Emissions Inventory (NAEI) emissions to model the concentrations of pollutants at the centroid of each 1km grid square, but then calibrates these concentrations in relation to actual monitoring data.

Pollutant background concentrations used for the purposes of this assessment have been obtained from the Defra supplied background maps for the relevant 1 km x 1 km grid squares covering the modelled domain for the year 2019. The relevant annual mean background concentration will be added to the predicted annual mean road contributions in order to predict the total pollutant concentration at each receptor location. The total pollutant concentration can then be compared against the relevant AQS objective to determine the event of an exceedance.

The Defra mapped background concentrations for base year of 2019, which cover the modelled domain, are presented in Table 3-3. All of the mapped background concentrations presented are well below the respective annual mean AQS objectives.

Table 3-3 – Defra Background Pollutant Concentrations in the AQMA

Grid Square (E,N)	2019 Annual Mean Background Concentration (µg/m ³) ¹			
	Total Background NO _x	Total Background NO ₂	Total Background PM ₁₀	Total Background PM _{2.5}
544500, 201500	25.2	18.1	17.9	11.1
Note: ¹ Values obtained from the 2019 Defra Mapped Background estimates for the relevant 1km x 1km grid squares covering the modelled domain				

¹⁰ Defra Background Maps (2019), available at <https://uk-air.defra.gov.uk/data/laqm-background-home>

4 Assessment Methodology

To predict pollutant concentrations of road traffic emissions the atmospheric model ADMS Roads version 5.0.0.1 was used to model a 2019 baseline scenario. The guiding principles for air quality assessments as set out in the latest guidance and tools provided by Defra for air quality assessment (LAQM.TG(16)¹ have been used.

The approach used in this assessment has been based on the following:

- Prediction of NO₂ concentrations at the two existing receptors within the AQMA and comparison with the relevant AQS objectives;
- Quantification of relative NO₂ contribution of sources to overall NO₂ pollutant concentration; and
- Determination of the geographical extent of any potential exceedances in regard to the existing AQMA boundary.

4.1 Traffic Inputs

Traffic flows and vehicle class compositions for the 2019 baseline scenario were taken from the following sources:

- Epping High Road - Provided by Epping Forest District Council as ANPR data allowing for detailed understanding of vehicle splits at the junction of the AQMA for 2019.
- M25 - The Department for Transport (DfT) traffic count point database for traffic for 2019.

Traffic speeds were modelled at either the relevant speed limit for each road or, where available, monitored vehicle speeds provided. Where appropriate, vehicle speeds have been reduced in accordance with LAQM TG(16)¹ to simulate queues at junctions, traffic lights and other locations where queues or slower traffic are known to be an issue. Congestion has been modelled at the junction by the AQMA by modelling the traffic speed at 5 km/h.

The Emissions Factors Toolkit (EFT) version 10.1 developed by Defra¹¹ has been used to determine vehicle emission factors for input into the ADMS-Roads model, based upon the traffic data inputs.

Details of the traffic flows used in this assessment including vehicle splits and Euro Class distribution are provided in Table B. 1 of the Appendices. The modelled road network is presented in Figure 4-4.

The traffic data provided by Aecom has been provided broken down by vehicle type and Euro class. The split of each vehicle type is shown in [Figure 4-1](#) below.

¹¹ Defra, Emissions Factors Toolkit. <https://laqm.defra.gov.uk/review-and-assessment/tools/emissions-factors-toolkit.html>

Figure 4-1 – Proportion of Vehicles on Epping High Road

A comparison of the observed Euro vehicles and the default UK fleet has been undertaken and is included below:

Figure 4-2 – Comparison of Observed ANPR data with UK Default Vehicle Fleet – Cars and LGVs

Figure 4-3 – Comparison of Observed ANPR data with UK Default Vehicle Fleet – HGVs

As shown above, the observed fleet typically contains more older vehicles (Euro 5 and below) than the default UK fleet and fewer new Euro 6 vehicles for all vehicle types.

The AQMA is located within 250 m of Bell Common Tunnel on the M25. Emissions from this tunnel will be considered using the Roads Tunnel module within ADMS Roads.

4.2 Sensitive Receptors

A total of two discrete receptors were included within the assessment to represent locations of relevant exposure at the two properties within the AQMA. Details of the receptors are presented within Table 4-1 and their locations are illustrated in Figure 4-5.

A receptor was included at ground floor at both properties within the AQMA.

Concentrations were also modelled across a regular gridded area, at a standardised ‘breathing zone’ height of 1.5 m, covering the full extent of the model domain. The intelligent gridding option was applied to the ADMS-roads model meaning additional points were added at locations close to the roads for greater output resolution.

Table 4-1 – Discrete Receptor Locations

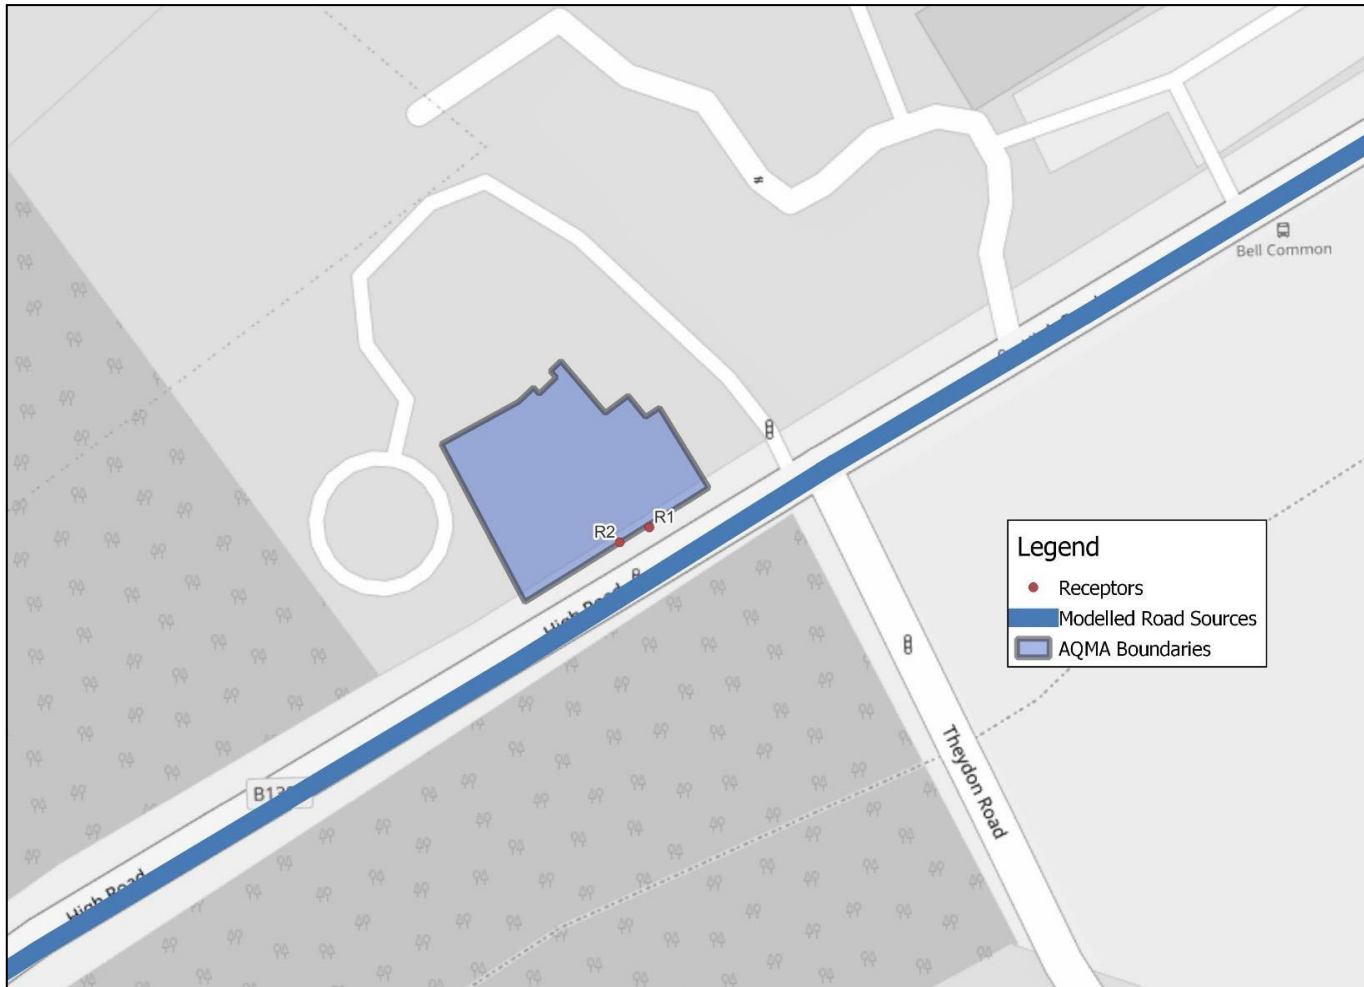

Receptor ID	X	Y	Height
R1	544928	201281	1.5
R2	544925	201279	1.5

Figure 4-5 – Modelled Receptors

Base map and data from OpenStreetMap and OpenStreetMap Foundation (CC-BY-SA). © <https://www.openstreetmap.org> and contributors.

4.3 General Model Inputs

A site surface roughness value of 0.5 m was entered into the ADMS-roads model, consistent with the parkland/open suburbia. In accordance with CERC’s ADMS Roads User Guide¹², a minimum Monin-Obukhov length of 10 m was used for the ADMS Road model to reflect the topography of the model domain.

One year of hourly sequential meteorological data from a representative synoptic station is required by the dispersion model. 2019 meteorological data from Stansted Airport weather station has been used in this assessment. The station is located approximately 23 km north of the AQMA and is considered representative of the meteorological conditions experienced throughout the borough. A surface roughness value of 0.5 m was used for the area surrounding the meteorological station, representative of the Stansted airfield location and surrounding buildings.

Within the modelled domain a review of topography was undertaken to establish whether it was required to include modelled road gradients. Following this review, it was considered to not be required.

A wind rose for this site for the year 2019 is shown in Figure 4-6.

Figure 4-6 – Wind rose for Stansted Data 2019

Most dispersion models do not use meteorological data if they relate to calm winds conditions, as dispersion of air pollutants is more difficult to calculate in these circumstances. ADMS-Roads treats calm wind conditions by setting the minimum wind speed to 0.75 m/s. It is recommended in LAQM.TG(16)¹ that the meteorological data file be tested within a dispersion model and the relevant output log file checked, to confirm the number of missing hours and calm hours that cannot be used by the dispersion model. This is important when considering predictions of high percentiles and the number of exceedances. LAQM.TG(16)¹ recommends that meteorological data should have a percentage of usable hours greater than 85%. If the data capture is less than 85% short-term concentration predictions should be expressed as percentiles rather than as numbers of exceedances. The 2019 meteorological data from Stansted includes 8,666 lines of usable hourly data out of the total 8,760 for the year, i.e. 98.9% usable data. This is therefore suitable for the dispersion modelling exercise.

4.4 Bell Common Tunnel

To account for the emissions from Bell Common Tunnel, the Road Tunnel Module within ADMS has been used. This involves creating an additional input file to account for emissions from both the entrance and exit of the Tunnel. The inputs for Bell Common Tunnel are included below. This has been completed in line with the CERC ADMS User Guide¹². This module has been validated using monitoring data gathered at Bell Common tunnel.

Table 4-2 – Additional Input File Tunnel Inputs

Name	Bell Common Tunnel
X1	544555.3

BoreDepth2	8
PortalBaseElev2	0
OutflowRoad2	M25 W of BCT
OutflowWidth2	32
OutflowWall2	No

4.5 Model Outputs

The background pollutant values discussed in Section 3.3 have been used in conjunction with the concentrations predicted by the ADMS-Roads model to calculate predicted total annual mean concentrations of NO_x.

For the prediction of annual mean NO₂ concentrations for the modelled scenarios, the output of the ADMS-Roads model for road NO_x contributions has been converted to total NO₂ following the methodology in LAQM.TG(16)¹, using the NO_x to NO₂ conversion tool developed on behalf of Defra. This tool also uses the total background NO_x and NO₂ concentrations. This assessment has used version 8.1 (August 2020) of the NO_x to NO₂ conversion tool¹³. The road contribution is then added to the appropriate NO₂ background concentration value to obtain an overall total NO₂ concentration.

The same process has been applied to provide annual mean concentrations for PM₁₀ and PM_{2.5}. As no Particulate Matter monitoring was available within the study area, the verification factor used for NO₂ has been applied.

In addition to annual mean concentrations, NO_x source apportionment was carried out for the following vehicle classes:

- Cars
- Taxis
- Light-Goods Vehicles (LGVs);
- Rigid Heavy-Goods Vehicles (HGVs)
- Articulated HGVs;
- Bus and Coaches;
- Motorcycles;
- Full Hybrid Petrol Cars;
- Plug-in Hybrid Petrol Cars;
- Full Hybrid Diesel Cars;
- Battery Electric Vehicle (EV) Cars; and,
- Battery EV LGVs.

Verification of the ADMS-Roads assessment has been undertaken using a number of local authority diffusion tube monitoring locations. All NO₂ results presented in the assessment are those calculated following the process of model verification. Full details of the verification process are provided in Appendix A – ADMS Model Verification.

¹³ Defra NO_x to NO₂ Calculator (2020), available at <https://laqm.defra.gov.uk/review-and-assessment/tools/background-maps.html#NOxNO2calc>

4.6 Uncertainty

Due to the number of inputs that are associated with the modelling of the study area there is a level of uncertainty that has to be taken into account when drawing conclusions from the predicted concentrations of NO₂. The predicted concentrations are based upon the inputs of traffic data, background concentrations, emission factors, street canyon calculations, meteorological data, modelling terrain limitations and the availability of monitoring data from the assessment area(s).

4.7 Uncertainty in NO_x and NO₂ Trends

Recent studies have identified historical monitoring data within the UK that shows a disparity between measured concentration data and the projected decline in concentrations associated with emission forecasts for future years¹⁴. Ambient concentrations of NO_x and NO₂ have shown two distinct trends over the past twenty-five years: (1) a decrease in concentrations from around 1996 to 2002/04, followed by (2) a period of more stable concentrations from 2002/04 rather than the further decline in concentrations that was expected due to the improvements in vehicle emissions standards.

The reason for this disparity is related to the actual on-road performance of vehicles, in particular diesel cars and vans, when compared with calculations based on the Euro emission standards. Preliminary studies suggest the following:

- NO_x emissions from petrol vehicles appear to be in line with current projections and have decreased by 96% since the introduction of 3-way catalysts in 1993;
- NO_x emissions from diesel cars, under urban driving conditions, do not appear to have declined substantially, up to and including Euro 5. There is limited evidence that the same pattern may occur for motorway driving conditions; and
- NO_x emissions from HDVs equipped with Selective Catalytic Reduction (SCR) are much higher than expected when driving at low speeds.

This disparity in the historical national data highlights the uncertainty of future year projections of both NO_x and NO₂.

Defra and the Devolved Administrations have investigated these issues and have since published updated versions of the EFT that utilise COPERT 5 emission factors, which may go some way to addressing this disparity, but it is considered likely that a gap still remains. This assessment has used the latest EFT version 10.1 and associated tools published by Defra to help minimise any associated uncertainty when forming conclusions from the results.

All tools used within the modelling process and baseline year of assessment used are based on assumptions prior to the COVID-19 pandemic. All assumptions made are based on the best understanding at the time of writing but there is the potential for behaviours to change in future as a result of a shift towards more flexible working or changes in uptake of newer vehicles.

5 Results

5.1 Modelled Concentrations

5.1.1 Baseline 2019 NO₂ Concentrations

The assessment has considered emissions of NO₂ from road traffic at the two existing receptor locations within the AQMA.

Table 5-1 provides a summary of the modelled receptors.

Table 5-1 – Summary of 2019 Modelled Receptor Results NO₂

Receptor ID	Modelled Annual Mean Concentration		
	NO ₂	PM ₁₀	PM _{2.5}
R1	52.2	20.6	12.9
R2	50.5	20.5	12.9
AQO	40	40	20

The modelled NO₂ results are slightly higher than the monitored concentration as a result of the difference in heights modelled and their positions relative to the road. The monitoring is located at 2 m height and the receptors at 1.5 m to represent typical ground floor windows.

Modelled concentrations of both PM₁₀ and PM_{2.5} are below the relevant national objectives.

Short Term

The empirical relationship given in LAQM.TG(16)¹ states that exceedances of the 1-hour mean objective for NO₂ is only likely to occur where annual mean concentrations are 60 µg/m³ or above at a location of relevant exposure (Table 2-1). Given the NO₂ annual mean concentration recorded at all receptors is below 60 µg/m³, exceedances of the hourly NO₂ AQS objective are unlikely.

Contour Plots

Modelled contour plots for total NO₂, PM₁₀ and PM_{2.5} annual mean concentrations are included below inclusive of both road and background concentrations at the modelled study area. Where there are exceedances of the relevant objective for NO₂ these areas are highlighted in green.

The contour plot is representative of gridded output from the ADMS model showing how the model has dispersed pollutants based on the sources input. This shows the spatial extent of pollutant concentrations as assumed in the model. The contour plots are inclusive of the model outputs and background concentrations and are subject to the same assumptions around verification and conversion from NO_x to NO₂.

Figure 5-1 – Annual Mean NO₂ Concentration Isoleth

Figure 5-2 – Annual Mean PM₁₀ Concentration Isoleth

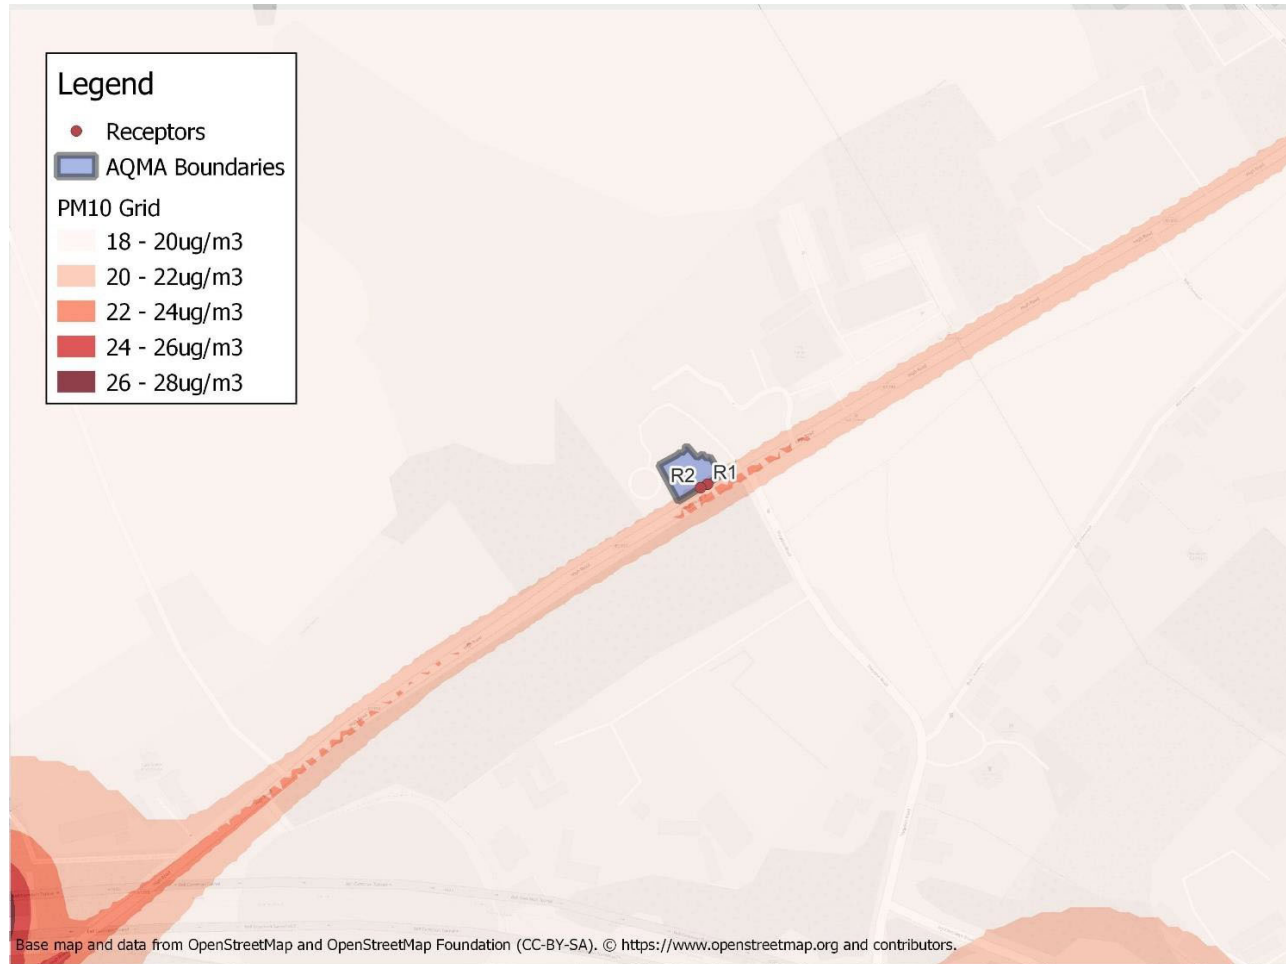

Figure 5-3 – Annual Mean PM_{2.5} Concentration Isoleth

5.1.2 Required Reduction in Emissions

In line with the methodology presented in Box 7.6 of TG(16)¹, the necessary reduction in Road NO_x and NO₂ emissions required to bring the current AQMA into compliance is calculated below, as shown in Table 5-2. This has been completed at the maximum annual mean concentration location, either monitored or modelled, for the existing AQMA. The TG(16) procedure calculates the required reduction of road NO_x to achieve a total NO₂ concentration of 40 µg/m³.

Table 5-2 – Required Reduction in NO_x and NO₂

Metric	Value (Concentrations as µg/m ³)
Worst-Case Relevant Exposure NO₂ Concentration	52.2
Equivalent NO_x Concentration	99.1
Background NO_x	25.2
Background NO₂	18.1
Road NO_x - Current	73.9
Road NO₂ - Current	34.1
Road NO_x - Required (to achieve NO₂ concentration of 39.9 µg/m³)	44.5
Road NO₂ - Required (to achieve NO₂ concentration of 39.9 µg/m³)	21.8
Required Road NO_x Reduction	29.4
Required Road NO₂ Reduction	12.3
Required % Reduction NO_x	39.8%

5.2 Estimated Year of Compliance

Following the identification of exceedances of the AQS objectives, it is useful to provide an estimate of the year by which concentrations at the identified locations of exceedances will become compliant with the relevant AQS objective. This is initially provided below assuming only the trends for future air quality, as currently predicted by Defra, are realised which should be treated with caution as it is expected that these will change as a result of the COVID-19 pandemic. The implementation of specific intervention measures to mitigate the local air quality issues, as are currently being developed by the Council within a revised AQAP, would then be considered most likely to bring forwards the estimated date of compliance.

Following the methodology outlined in LAQM.TG(16)¹ paragraph 7.70 onward, the year by which concentrations at the identified locations of exceedances will become compliant with the NO₂ annual mean AQS objective has been estimated. This has been completed using the predicted modelled NO₂ concentrations from the 2019 Base scenario.

As a worst-case approach, the projection is based upon the monitoring from 2019 predicted as having the maximum annual mean NO₂ concentration at R1. The appropriate roadside NO₂ projection factors, as provided on the LAQM Support website¹⁵, are then applied to this

¹⁵ <https://laqm.defra.gov.uk/tools-monitoring-data/roadside-no2-projection-factor.html>

concentration value to ascertain the estimated NO₂ annual mean reduction per annum, and hence the anticipated year of compliance. In this case, roadside projection factors for 'Rest of UK (HDV <10%)' have been applied, consistent with the receptor location.

The projected NO₂ annual mean concentrations following the above approach are presented in Table 5-3.

Table 5-3 – Projected Annual Mean NO₂ Concentrations

Receptor 1							
2019 Annual Mean Concentration (µg/m ³)	Predicted Annual Mean Concentration (µg/m ³)						
	2020	2021	2022	2023	2024	2025	2026
52.2	49.6	46.8	44.2	41.9	39.7	37.6	35.8
In bold , exceedance of the NO ₂ annual mean AQS objective of 40µg/m ³ Vehicle Adjustment Factor = Rest of UK (HDV <10%)							

Table 5-3 indicates that the first year by which Receptor 1 will be exposed to a concentration below the annual mean NO₂ AQS objective will be 2024 at the very earliest. Concentrations are expected to be below 10% of the annual mean NO₂ AQS objective at the very earliest by 2026.

It should be noted that these calculations are made based on assumptions which were correct prior to the COVID-19 pandemic and so the results should be treated with caution.

5.3 Source Apportionment

5.3.1 Background Source Apportionment

The Defra maps provide high level source apportionment for a number of different emissions sources. For the background map square within which the AQMA is located the breakdown of sources is shown below for NO_x, PM₁₀ and PM_{2.5}.

'Other' sources are defined as per the Background Maps user guide as 'ships, off-road and other emissions'. 'Point Sources' are those which come are defined as emissions of a known amount from a known location (e.g. a power station) but do not fall under the 'Industry' source category.

Secondary PM is defined as any inorganic and organic aerosol sources of particulate matter and 'Residual + Salt is inclusive of Sea Salt, calcium and iron rich dusts and regional primary PM and residual non-characterised sources.

Table 5-4 – NO_x Background Source Apportionment

	Motorway	Trunk Road	Primary Road	Minor Road	Industry	Domestic	Aircraft	Rail	Other	Point Sources	Rural
NO_x Concentration (µg/m³)	11.0	<0.1	1.6	1.5	1.1	1.4	<0.1	<0.1	0.4	0.6	7.7
Percent of Background NO_x	43.4	0.1	6.2	6.1	4.3	5.5	<0.1	0.2	1.5	2.2	30.5

Table 5-5 – PM₁₀ and PM_{2.5} Background Source Apportionment

	Motorway	Trunk Road	Primary Road	Minor Road	Brake & Tyre Wear	Road Abrasion	Industry	Domestic	Rail	Other	PM Secondary	Residual & Salt	Point Sources
PM₁₀ Concentration (µg/m³)	<0.1	<0.1	<0.1	<0.1	0.3	0.2	0.7	0.5	<0.1	<0.1	7.3	8.7	<0.1
Percent of Background PM₁₀	0.5	<0.1	<0.1	<0.1	1.5	1.3	3.9	2.9	<0.1	0.3	40.7	48.6	0.2
PM_{2.5} Concentration (µg/m³)	<0.1	<0.1	<0.1	<0.1	<0.1	<0.1	0.3	0.5	<0.1	<0.1	6.2	3.6	<0.1
Percent of Background PM_{2.5}	0.7	<0.1	<0.1	0.2	1.3	1.1	2.5	4.7	<0.1	0.5	56.1	32.5	0.3

As shown above, the motorway makes up around 43% of the background NO_x concentration within the grid square containing the AQMA. PM₁₀ and PM_{2.5} concentrations are mainly made up of Residual and secondary emissions.

5.3.2 Vehicle Type and Age

To help inform the development of measures as part of the action plan stage of the project, a NO_x source apportionment exercise was undertaken for the following vehicle classes:

- Cars
- Taxis
- Light-Goods Vehicles (LGVs);
- Rigid Heavy-Goods Vehicles (HGVs)
- Articulated HGVs;
- Bus and Coaches;
- Motorcycles;
- Full Hybrid Petrol Cars;
- Plug-in Hybrid Petrol Cars;
- Full Hybrid Diesel Cars;
- Battery Electric Vehicle (EV) Cars; and,
- Battery EV LGVs.

This will provide vehicle emission proportions of NO_x that will allow the Council to design specific AQAP measures targeting a reduction in emissions from specific vehicle types.

It should be noted that emission sources of NO₂ are dominated by a combination of direct NO₂ (f-NO₂) and oxides of nitrogen (NO_x), the latter of which is chemically unstable and rapidly oxidised upon release to form NO₂. Reducing levels of NO_x emissions therefore reduces levels of NO₂. As a consequence, the source apportionment study has considered the emissions of NO_x which are assumed to be representative of the main sources of NO₂.

The source apportionment study has also included PM₁₀ and PM_{2.5}.

The age of vehicles has been determined by accounting for the 'Euro Class' they are assigned.

Table 5-6 – Detailed Source Apportionment of NO_x Concentrations at R1

Results	All Vehicles	Petrol Car	Diesel Car	Taxis	Petrol LGV	Diesel LGV	Rigid HGV	Artic HGV	Buses/ Coaches	Motorcycle	Full Hybrid Petrol Cars	Plug-in Hybrid Petrol Cars	Full Hybrid Diesel Cars	Battery EV Cars	Battery EV LGVs	Background

NO_x

The following observations can be made:

- Road traffic accounts for 73.9 µg/m³ (74.5%) of total NO_x (99.1 µg/m³), with background accounting for 25.2 µg/m³ (25.5%);
- Of the total road NO_x, the contribution of Petrol and Diesel Cars (32.%), Petrol and Diesel LGVs (31.1%) and Rigid and Artic HGVs including Buses and Coaches (34.8%) are split fairly evenly making up the total road NO_x;
- Of the cars included in the model, Diesel cars account for 28.5% of Road NO_x where Petrol cars account for only 4.4% and Taxis 1.1%;
- Of the LGVs, Diesel LGVs account for 31.1% of road NO_x emissions and Petrol LGVs >0.1%;
- Rigid HGVs account for 26.6% of Road NO_x compared to Articulated HGVs which account for only 5.6% and Buses/Coaches only 2.5%
- Motorcycles are found to contribute <1%; and
- Hybrid Vehicles account for only 0.2% of Road NO_x.

The NO_x source apportionment exercise demonstrates Diesel Cars and LGVs being the primary contributors to road NO_x concentrations within the AQMA.

PM₁₀ and PM_{2.5}

PM₁₀ and PM_{2.5} concentrations within the AQMA are largely made up of residual background sources. For both pollutants, the greatest road contributor was identified as being Diesel Cars, followed by Petrol cars and Diesel LGVs.

5.3.3 Congestion in AQMA

To achieve a verified model, the link within the AQMA has been modelled at 5 km/h in line with TG(16) to be representative of congestion and queueing traffic at this junction where vehicles are stopped as a result of traffic lights. The contribution from those links which have been modelled at slower speeds as a result of congestion and those with free-flowing traffic are compared below.

Pollutant		Congested Roads	Free Flowing Roads
NO _x	Total Road NO _x (µg/m ³)	60.5	13.4
	Percent of Total Road NO _x	81.9	18.1
PM ₁₀	Total Road PM ₁₀ (µg/m ³)	1.10	0.49
	Percent of Total Road PM ₁₀	69.3	30.7
PM _{2.5}	Total Road PM _{2.5} (µg/m ³)	0.76	0.32
	Percent of Total Road PM _{2.5}	70.6	29.4

It should be noted that the receptor used as representative of the worst-case location within the AQMA is located closest to a road with congestion, so it is to be expected that this would account for the majority of contributions to the total concentration.

Figure 5-11 – Source Apportionment of Road Congestion

6 Conclusions

The dispersion modelling exercise undertaken has provided the following updated perspective on NO₂ challenges within the Epping Forest AQMA.

6.1 Predicted Concentrations

All of receptors reporting NO₂ annual mean concentrations to be above or within 10% of the AQS objective limit are either located within the existing AQMA or are concentrated to roadside locations of junctions where key arterial roads meet and form the main transportation network within the region.

The highest annual mean concentration of NO₂ was recorded at R1 with a concentration of 52.2 µg/m³. This is slightly higher than the adjacent recorded monitoring which recorded 48 µg/m³ as a result of a slightly lower modelling height and its position relative to the road.

The empirical relationship given in LAQM.TG(16)¹ states that exceedances of the 1-hour mean objective for NO₂ is only likely to occur where annual mean concentrations are 60 µg/m³ or above at a location of relevant exposure. Given the NO₂ annual mean concentration recorded at all receptors is below 60 µg/m³, exceedances of the hourly NO₂ AQS objective are unlikely.

PM₁₀ and PM_{2.5} concentrations have also been predicted as part of the modelling assessment. No modelled receptors recorded concentrations in exceedance of either of the annual mean objectives for these pollutants. The highest modelled PM₁₀ concentration was 20.6 µg/m³ at R1. The highest modelled PM_{2.5} concentration was 12.9 µg/m³ at R1.

6.2 Estimated Year of Compliance

Using the recommended method in TG(16), the estimated year of compliance within the AQMA should no additional measures be put in place is 2024 and will be below 10% of the AQO by 2026.

6.3 Source Apportionment

To help inform the development of measures as part of a future AQAP, a NO_x source apportionment exercise was undertaken to provide an understanding of any potential similarities in vehicle emission contributors within the AQMA.

Petrol Cars were the most prevalent vehicles on the road within the AQMA, 46.6% of all vehicles were petrol cars. The fleet makeup, as determined by the ANPR survey, also indicated that vehicles using High Road Epping were made up of older vehicles than the default fleet assumption within the EFT derived from the National Air Emissions Inventory (NAEI).

The NO_x source apportionment exercise demonstrates Diesel Cars and Diesel LGVs being the primary contributors to road NO_x concentrations within the AQMA. The split between overall car, LGV and HGV emissions was roughly equal with each contributing around a third to total road NO_x.

An assessment of queueing traffic showed that, within the AQMA, congestion accounts for 81.9% of NO_x contributions from the road. Should any traffic smoothing measures be introduced, this is likely to reduce pollutant concentrations within the AQMA.

PM₁₀ and PM_{2.5} concentrations within the AQMA are largely made up of residual background sources. For both pollutants, the greatest road contributor was identified as being Diesel Cars, followed by Petrol cars and Diesel LGVs..

Appendices

Appendix A – ADMS Model Verification

The ADMS-Roads dispersion model has been widely validated for this type of assessment and is specifically listed in the Defra's LAQM.TG(16)¹ guidance as an accepted dispersion model.

Model validation undertaken by the software developer (CERC) will not have included validation in the vicinity of the AQMA. It is therefore necessary to perform a comparison of modelled results with local monitoring data at relevant locations. This process of verification attempts to minimise modelling uncertainty and systematic error by correcting modelled results by an adjustment factor to gain greater confidence in the final results.

The predicted results from a dispersion model may differ from measured concentrations for a large number of reasons, including uncertainties associated with:

- Background concentration estimates;
- Source activity data such as traffic flows and emissions factors;
- Monitoring data, including locations; and
- Overall model limitations.

Model verification is the process by which these and other uncertainties are investigated and where possible minimised. In reality, the differences between modelled and monitored results are likely to be a combination of all of these aspects.

Model setup parameters and input data were checked prior to running the models in order to reduce these uncertainties. The following were checked to the extent possible to ensure accuracy:

- Traffic data;
- Distance between sources and monitoring as represented in the model;
- Speed estimates on roads;
- Background monitoring and background estimates; and
- Monitoring data.

The traffic data for this assessment has been collated using a combination of data provided by the highways department at GCC and DfT traffic count data, as outlined in Section 4.1.

The details of the LAQM monitoring sites considered for the purposes of model verification are presented in [Table A.1](#) below.

Table A.1 – Local Monitoring Data Available for Model Verification

Site ID	OS Grid Reference		2019 Annual Mean NO ₂ Concentration (µg/m ³)	2019 Data Capture (%)
	X	Y		
3	544928	201281	48.0	100
33	544709	201139	31.0	100

NO₂ Verification Calculations

The verification of the modelling output was performed in accordance with the methodology provided in Chapter 7 of LAQM.TG(16)¹. For the verification and adjustment of NO_x/NO₂, the 2019 monitoring data presented in [Table A.1](#) was used.

Verification was completed using the 2019 (2018 reference year) Defra background mapped concentrations for the relevant 1 km x 1 km grid squares within Epping Forest (i.e. those within which the model verification locations are located), as displayed in [Table 3-3](#).

Table A.2 below shows an initial comparison of the monitored and unverified modelled NO₂ results for the year 2019, in order to determine if verification and adjustment was required. [Figure A-1](#) shows this data graphically.

Table A.2 – Comparison of Unverified Modelled and Monitored NO₂ Concentrations

Site ID	Background NO ₂	Monitored total NO ₂ (µg/m ³)	Unverified Modelled total NO ₂ (µg/m ³)	Difference (modelled vs. monitored) (%)
3	15.3	48.0	36.1	-24.8
33	15.3	31.0	28.0	-9.8

Figure A-1 – Unverified Comparison of the Modelled Road Contribution NO_x versus Monitored Road Contribution NO_x

The data in the table above show that the model was under predicting at both verification points, with the highest under prediction between the modelled and monitored concentrations observed at Site 3 (-24.8 %). At this stage all model inputs were checked to ensure their accuracy, this includes road and monitoring site geometry, traffic data, link emission rates, 2019 monitoring results, background concentrations and modelling features such as street canyons. Following a level of QA/QC completed upon the model, no further improvement of the modelled results could be obtained on this occasion. The difference between modelled and monitored concentrations was almost 25% at the monitoring location within the AQMA, therefore adjustment of the results was necessary. The relevant data was then gathered to allow the adjustment factor to be calculated.

Model adjustment needs to be undertaken based on NO_x and not NO₂. For the Council operated monitoring results used in the calculation of the model adjustment, NO_x was derived from NO₂; these calculations were undertaken using a spreadsheet tool available from the LAQM website¹⁶.

¹⁶ <http://laqm.defra.gov.uk/review-and-assessment/tools/background-maps.html#NOxNO2calc>

Verification (AQMA)

Table A.3 provides the relevant data required to calculate the model adjustment based on regression of the modelled and monitored road source contribution to NO_x.

Figure A-2 provides a comparison of the Modelled Road Contribution NO_x versus Monitored Road Contribution NO_x, and the equation of the trend line based on linear regression through zero. The Total Monitored NO_x concentration has been derived by back-calculating NO_x from the NO_x/NO₂ empirical relationship using the spreadsheet tool available from Defra's website. The equation of the trend lines presented in gives an adjustment factor for the modelled results of 1.713.

Table A.3 – Data Required for Adjustment Factor Calculation

Site ID	Monitored total NO ₂ (µg/m ³)	Monitored total NO _x (µg/m ³)	Background NO ₂ (µg/m ³)	Background NO _x (µg/m ³)	Monitored road contribution NO ₂ (total - background) (µg/m ³)	Monitored road contribution NO _x (total - background) (µg/m ³)	Modelled road contribution NO _x (excludes background) (µg/m ³)
3	48.0	90.6	18.1	25.2	29.9	65.4	36.1
33	31.0	51.1	18.1	25.2	12.9	25.9	19.1

Figure A-2 – Comparison of the Modelled Road Contribution NO_x versus Monitored Road Contribution NO_x

Table A.4 – Adjustment Factor and Comparison of Verified Results against Monitoring Results

Site ID	Ratio of monitored road contribution NO _x / modelled road contribution NO _x	Adjustment factor for modelled road contribution NO _x	Adjusted modelled road contribution NO _x (µg/m ³)	Adjusted modelled total NO _x (including background NO _x) (µg/m ³)	Modelled total NO ₂ (based upon empirical NO _x / NO ₂ relationship) (µg/m ³)	Monitored total NO ₂ (µg/m ³)	Difference (adjusted modelled NO ₂ vs. monitored NO ₂) (%)
3	1.81	1.713	61.8	87.0	47.3	48.0	-1.4
33	1.36		32.7	57.9	34.5	31.0	11.4

Figure A-3 – Comparison of the Verified Modelled Total NO₂ versus Monitored NO₂

Table A.4 and Figure A-3 show the ratios between monitored and modelled NO₂ for each monitoring location after using the calculated adjustment factor. LAQM.TG(16)¹ states that:

“In order to provide more confidence in the model predictions and the decisions based on these, the majority of results should be within 25% of the monitored concentrations, ideally within 10%.”

The sites show good agreement between the ratios of monitored and modelled NO₂. It can be seen that the verification point within the AQMA is within ±10% tolerance as detailed in LAQM.TG(16), and is less than 1% different. Monitoring at Site 33 is just outside of 10% difference and within the acceptable 25% tolerance.

A factor of 1.713 reduces the Root Mean Square Error (RMSE) from a value of 40.4 to 2.5, which is in line with the guidance value of 4 µg/m³ as stated within LAQM.TG(16).

The adjustment factor was applied to the road contribution NO_x and PM concentrations predicted by the model to arrive at the final NO₂ concentrations in the AQMA.

Appendix C:

Epping Forest District Council Response to TfL Consultation on Proposals to Extend the Ultra Low Emission Zone (ULEZ)

Epping Forest District Council Response to TfL Consultation on Proposals to Extend the Ultra Low Emission Zone (ULEZ) London-wide From 29 August 2023

Background

Population and transportation in Epping Forest District

Epping Forest District is in the south-west of Essex abutting both Hertfordshire and Greater London, specifically the London boroughs of Waltham Forest, Enfield, Redbridge, and Havering. Based on ONS data from 2021, the District has a population of around 135,000.

The south-west of the District is served by the London Underground Central Line (both the main line and the 'Hainault via Newbury Park' loop). Epping Station is the eastern terminus and there are 7 other stations in service in the District. There is one national railway station in the District – at Roydon on the Liverpool Street to Stansted and Cambridge line, although other railway stations (Broxbourne, Sawbridgeworth, Harlow Town and Harlow Mill) are close to, and accessible from, the District. The Central Line used to run further than Epping through stations at North Weald and Blake Hall to the end of the line at Ongar. Blake Hall station closed in 1981 with the line closing in 1994.

Some areas of the District have relatively good transport links with both the M11 and M25 motorways running through the area and the A406 being a short distance from

the south of the District. However, in the rural areas there are accessibility issues for some without private transport, especially in outlying villages. In addition, making east-west trips across the District by public transport is extremely challenging.

Around half of the District's working residents commute out of the District for work, with the largest proportion travelling to London.

Air quality in the District

Air quality in the District in relation to human health is generally good with nitrogen dioxide (NO₂) and particulates (PM₁₀) levels below the UK legal limit value for these pollutants. The District does have one air quality management area (AQMA) declared for exceedances of the 1 hour mean and annual mean for NO₂ near the B1393/ Theydon Road junction at Epping, Bell Common attributed to vehicle emissions. Source apportionment work conducted by Bureau Veritas on behalf of the Council in December 2021 concluded that by 2024, our AQMA for NO₂ will be in compliance with the air quality limit values. It further concluded that NO₂ concentrations will be below 10% of the air quality limit value by 2026.

The District, together with the London Boroughs of Waltham Forest and Redbridge, also has a Special Area of Conservation (SAC) which is an international designation applied to sites whose habitats and species have significant ecological importance. The Epping Forest SAC (EFSAC) is sensitive to pollutants which include oxides of nitrogen (NO_x) and ammonia (NH₃) and because of this, there are pollutant critical levels set for these pollutants. With respect to the EFSAC, vehicle tailpipe emissions are the main source of pollution (with catalytic convertors being the primary source of NH₃). It is known that much of the EFSAC is in an unfavourable condition. Under the UK legislation the Council is a competent authority with a duty to ensure that plans and projects can only be permitted where there will be no adverse effect either alone or in combination with other plans and projects on the Forest. This is a matter which has been the subject of considerable and ongoing discussion as part of the examination into the Council's emerging Local Plan in order to shape an appropriate policy framework to mitigate the effect of new development on the EFSAC. In addition, to support the delivery of new development Epping Forest District Council has produced an [Air Pollution Mitigation Strategy](#) (which is currently an Interim

Strategy), which provides a list of measures to be implemented in order to mitigate any effects on the EFSAC. One such measure, should it be demonstrated to be necessary through on-site monitoring and subsequent air quality modelling, is the creation of an EFSAC specific Clean Air Zone.

As part of the work to assess air pollution impacts on the EFSAC, ANPR data was obtained to assess fleet composition. It found that in terms of euro class split, the 2019 ANPR data showed that the car and LGV fleet using the roads through the EFSAC is for the main part newer than that in the EFT outer London fleet, but older than the EFT UK average outside of London. Older vehicles with less rigorous euro standards are typically more prevalent in the local vehicle fleet for both 2017 and 2019 ANPR surveys.

Climate Change Emergency

Epping Forest District Council declared a climate emergency in September 2019 and made a commitment to do everything within its power to become a carbon neutral District by 2030. A Climate Change Action Plan has recently been adopted by the Council. Actions to address air quality and climate change are closely linked, so many of the measures in our Climate Change Action Plan will also support improvements in air quality in the District and have beneficial effects on both human health and the EFSAC. As 65% of the District's carbon emissions come from on road transport sources, maximising opportunities to make it easier for residents and businesses to transition to using Ultra Low Emissions Vehicles (ULEV's), encouraging sustainable transport choices and reducing the number of journeys made by vehicles is a major component of this Plan.

Response to the ULEZ expansion consultation

Epping Forest District Council welcomes the opportunity to respond to this consultation. As seen from our background information above, we share a common goal of improving air quality and reducing carbon emissions. With the south of our District bordering three London boroughs and being in close proximity to the A406, the expansion of the ULEZ will undoubtedly have a direct impact on our District.

Having reviewed the consultation documents, in principle we support the aims of the expansion put forth by TfL but also have concerns that TfL and the Mayor of London need to address.

Concern 1: Traffic displacement

Insufficient information has been provided to demonstrate that Epping Forest District would not be impacted by drivers avoiding the ULEZ boundary. The present ULEZ has a clear boundary (A406) which allows drivers to avoid the ULEZ whilst also avoiding residential roads however, the proposed new boundary is not as defined and provides more opportunities for drivers to divert to residential roads and use alternative routes to get to their destinations. Additionally, there is a concern that drivers from both our District and outside who currently drive into London may decide to park near a tube station in our District to avoid paying to enter the London wide ULEZ. This in turn can result in increased vehicle movements in our District and the creation of congestion and pollution hot spots.

Action requested:

We ask that TfL model for this or at least provide additional information to demonstrate whether the hypothesis of traffic displacement is valid and if so, propose measures to mitigate the negative impacts. Without this information, Epping Forest District Council would not be able to support the ULEZ expansion.

Concern 2: Creation of pollution corridor

We do not believe that the mitigation measures put forth in our Interim Air Pollution Mitigation Strategy were fully taken into consideration by TfL when modelling the impacts of the proposed ULEZ expansion. One such measure, a clean air zone in conjunction with the proposed ULEZ expansion may create a pollution corridor in the areas of the District caught between the two boundaries.

Action requested:

We ask that TfL model for this or at least provide further information to demonstrate if the hypothesis of a pollution corridor is valid and if so, propose measures to mitigate the negative impacts. Without this information, Epping Forest District Council would not be able to support the ULEZ expansion.

Concern 3: Impact on our air quality management area

Whilst the modelling produced by TfL goes up to the M25 boundary, our AQMA is just outside of this boundary and we are therefore not able to assess the impact of the expansion on our AQMA. The additional information provided to us by TfL states that the scheme is not expected to increase NO_x emissions on any road links within Epping Forest or within the Epping Forest Areas but the way the data is presented suggests that the data for the A roads, B roads, etc, have been averaged. It is therefore difficult to assess if the ULEZ expansion will increase NO₂ levels in and around our AQMA and delay the time it will take to revoke it.

Action requested:

We ask that TfL provide more detailed information regarding the proposed ULEZ expansion's impact on our AQMA and whether this expansion will delay the time it will take for our AQMA to be revoked. Without this information, Epping Forest District Council would not be able to support the ULEZ expansion.

Concern 4: Impact on the Epping Forest Special Area of Conservation

The ULEZ may influence people to upgrade their vehicles or switch from diesel to petrol. Whilst this may be beneficial with regards to reducing NO₂ and particulate tail pipe emissions, it may result in an increase in ammonia levels as ammonia is a product released by catalyst-equipped petrol vehicles and selective catalytic reduction (SCR) on both light and heavy-duty diesel vehicles. Ammonia is a pollutant of concern for the EFSAC. The additional information provided by TfL states that while ammonia emissions have not been modelled, the baseline proportion of electric vehicles in their model inputs are considerably higher than that assumed in the modelling undertaken to inform the Habitats Regulations Assessment 2021 (HRA 2021) undertaken to support the main modifications to our emerging Local Plan and our Interim Air Pollution Mitigation Strategy. Therefore TfL have suggested that ammonia levels are expected to result in an earlier achievement of the targets set out in the HRA 2021 and the Interim Air Pollution Mitigation Strategy. We feel that a baseline proportion of EV's in the range of 40-50% from 2030 is optimistic and feel

that instead there will be an increase in petrol vehicles. This is supported by the follow up response provided by TfL that acknowledges a potential increase in the proportion of compliant petrol vehicles. This is a matter of importance as there is a need under the Habitats and Species Regulations to take a 'precautionary' approach. The HRA 2021 and Interim Air Pollution Mitigation Strategy set out that, based on current available information, a 30% reduction in petrol cars (such that 12-15% of all vehicles using roads through the EFSAC are ULEVs by that year) would need to be achieved by 2033 in addition to any Clean Air Zone to be able to demonstrate no adverse effect on the integrity of the EFSAC as a result of Local Plan development. The EFSAC ANPR data collected in 2019 also showed that the proportion of the vehicle fleet was 43.8% petrol car as opposed to 31.5% of diesel cars.

Action requested:

We ask that TfL model for the impact of the ULEZ expansion on the EFSAC in relation to ammonia concentrations. Without this information, Epping Forest District Council would not be able to support the ULEZ expansion.

Concern 5: Impact on the current public transport system and road network

Over the past years, TfL has reduced service within our District. The time between tube trains has been increased and some bus routes have been reduced or removed. Should residents decide to use public transport instead of drive, this will add further strain on the public transport system in our District. Conversely, as a result of service reductions some residents may use their cars rather than public transport. This undermines modal shift objectives and could exacerbate vehicle queue lengths within the EFSAC and around our AQMA which could potentially impact on the achievement of our air quality targets.

Action requested:

We ask that TfL keep the provision of public transport in our District under review to ensure that residents and people who commute to and from our District for work, education and leisure are not negatively affected should commuter usage increase as a result of the ULEZ expansion; and to avoid an increase in vehicular traffic in our District.

Concern 6: Insufficient time and scrappage scheme

It appears that the scrappage scheme proposed to support the ULEZ expansion will only be available to London residents. Additionally, the implementation target date of August 2023 will provide little time for residents and businesses to plan for purchasing a new vehicle, especially during the current difficult economic period. The current delays of receiving new vehicles due to production issues caused by the pandemic, global shortage of key microprocessor chips and the war in Ukraine should also be taken into consideration.

Action requested:

We ask that TfL and the Mayor of London expand the scrappage scheme radius to boroughs/Districts that directly border the Greater London border to maximise the effectiveness of the scheme. We also ask that a sunset period extending past the August 2023 implementation date is offered to residents and businesses who reside/operate in boroughs/Districts that directly border Greater London.

Concern 7: Poor provision of EV charge points in TfL car parks

There are 8 London Underground Line stations within the District (Epping, Theydon Bois, Debden, Loughton, Buckhurst Hill, Roding Valley, Chigwell and Grange Hill). Presently the TfL car park at Theydon Bois is the only one that offers charging points for taxis.

Action requested:

We ask that TfL install EV charge points for taxis and public use at their car parks situated in our District.

Glossary of Terms

Abbreviation	Description
AQAP	Air Quality Action Plan - A detailed description of measures, outcomes, achievement dates and implementation methods, showing how the local authority intends to achieve air quality limit values'
AQFA	Air Quality Focus Area
AQMA	Air Quality Management Area – An area where air pollutant concentrations exceed / are likely to exceed the relevant air quality objectives. AQMAs are declared for specific pollutants and objectives
AQO	Air Quality Objectives
AQS	Air Quality Strategy
ASR	Air Quality Annual Status Report
Defra	Department for Environment, Food and Rural Affairs
EU	European Union
EFSAC	Epping Forest Special Area of Conservation
EFDC	Epping Forest District Council
ECC	Essex County Council
GLA	Greater London Authority
HRA	Habitats Regulation Assessment
LAQM	Local Air Quality Management
NO ₂	Nitrogen Dioxide

NO _x	Nitrogen Oxides
PHOF	Public Health Outcomes Framework
PM ₁₀	Airborne particulate matter with an aerodynamic diameter of 10µm (micrometres or microns) or less
PM _{2.5}	Airborne particulate matter with an aerodynamic diameter of 2.5µm or less
SHAPE	Strategic Health Asset Planning and Evaluation
TfL	Transport for London
WHO	World Health Organization
µg/m ³	The concentration of an air pollutant (eg. Nitrogen dioxide) is given in micrograms (one-millionth of a gram) per cubic meter air
